

## Lecture 2: Modern Flow of Control

### 0 Motivation

Normally, a program executes statements from first to last. The first statement is executed, then the second, then the third, and so on, until the program reaches its end. Sometimes, a computer program *looks* as though it is very similar to a run-the-same-sequence-of-statements-from-first-to-last-run. It would be nice to be able to change which statements run and when, depending on the circumstances. For example, if a program checks to see for the number of times a certain word appears, it should be able to give the correct count no matter what the word being given is. Or, a computer game should move the player's character around when the player wants, the need to be able to alter the order in which a program's statements are executed, the control flow.

### 1 Control Structures

Control structures are portions of program code that execute statements either from end to beginning or the circumstances, execute these statements in a certain way. There are typically two kinds: conditionals and loops.

#### 1.1 Conditionals

In order for a program to change its behavior depending on the input, there must a way to test that input. Conditionals allow the program to check the values of variables and to execute (or not execute) certain statements. C, C++, Java, and several other popular structures.

##### 1.1.1 Operators

Conditionals use two kinds of special operators: relational and logical. These are used to determine whether some condition is true or false.

The relational operators are used to test a relation between two expressions:

Operator	Meaning
>	Greater than
>=	Greater than or equal to
<	Less than
<=	Less than or equal to
==	Equal to
!=	Not equal to

They work the same as the arithmetic operators (e.g.,  $a + b$ ) that return a numeric value of either zero or nonzero, indicating whether the operator tested for true. (An expression that returns zero and no value is called a Boolean expression.) For example, if the variables  $x$  and  $y$  have been set to 5 and 1, respectively, then  $x > y$  returns true. Similarly,  $x < y$  returns false.

The logical operators are often used to combine relational expressions into more complicated Boolean expressions.
