Lecture 2 Notes: Flow of Control

1   Motivation

Normally, a program executes statements from first to last. The first statement is executed, then the second, then the third, and so on, until the program reaches its end and terminates. A computer program isn't really that useful if it ran the same sequence of statements every time it was run. It would be nice for it to be able to change which statements ran and when, depending on the circumstances. For example, if a program checks a file for the number of times a certain word appears, it should be able to give the correct count no matter what file and word are given to it. Or, in a computer game should move the player's character around when the player wants, we need to be able to alter the order in which a program's statements are executed, the control flow.

2   Control Structures

Control structures are portions of program code that contain statements within them and, depending on the circumstances, execute these statements in a certain way. There are typically two kinds: conditionals and loops.

2.1   Conditionals

In order for a program to change its behavior depending on the input, there must a way to test that input. Conditionals allow the program to check the values of variables and to execute (or not execute) certain statements. C++ has if and switch-case conditional structures.

2.1.1   Operators

Conditionals use two kinds of special operators: relational and logical. These are used to determine whether some condition is true or false.

The relational operators are used to test a relation between two expressions:

Operator	Meaning
>	Greater than
>=	Greater than or equal to
<	Less than
<=	Less than or equal to
==	Equal to
!=	Not equal to

They work the same as the arithmetic operators (e.g. $+$ or $*$) but return a Boolean value of either true or false, indicating whether the relation tested for holds. (An expression that returns this kind of value is called a Boolean expression.) For example, if the variables x and y have taken set to 6 and 1, respectively, then $x > y$ returns true. Similarly, $x < y$ returns false.

The logical operators are often used to combine relational expressions into more complicated Boolean expressions:
