

## Chapter 50: Sensory and Motor Mechanisms

- Sensory receptors transduce stimulus energy and transmit signals to the central nervous system.
  - The detection of a stimulus precedes sensory transduction, the change in the membrane potential of a sensory receptor in response to a stimulus. The resulting receptor potential controls transmission of action potentials to the CNS, where sensory information is integrated to generate perceptions. The frequency of action potentials in an axon and the number of axons activated reflect stimulus strength. The identity of the axon carrying the signal encodes the nature or quality of the stimulus.
  - Mechanoreceptors respond to stimuli such as pressure, touch, stretch, motion, and sound. Chemoreceptors detect either total solute concentrations or specific molecules. Electromagnetic receptors detect different forms of electromagnetic radiation. Thermoreceptors signal surface and core temperatures of the body. Pain is detected by a group of nociceptors that respond to excess heat, pressure, or specific classes of chemicals.
- In hearing and equilibrium, mechanoreceptors detect moving fluid or settling particles.
  - Most invertebrates sense their orientation with respect to gravity by means of statocysts. Specialized hair cells form the basis for hearing and balance in mammals and for detection of water movement in fishes and aquatic amphibians. In mammals, the tympanic membrane (eardrum) transmits sound waves to bones of the middle ear, which transmit the waves through the oval window to the fluid in the coiled cochlea of the inner ear. Pressure waves in the fluid vibrate the basilar membrane, depolarizing hair cells and triggering action potentials that travel via the auditory nerve to the brain. Receptors in the inner ear function in balance and equilibrium.
- The diverse visual receptors of animals depend on light-absorbing pigments.
  - Invertebrates have varied light detectors, including simple light-sensitive eyespots, image-forming compound eyes, and single-lens eyes. In the vertebrate eye, a single lens is used to focus light on photoreceptors in the retina. Both rods and cones contain a pigment, retinal, chemically bonded to a protein (opsin).
