Nonlinear Finite Element Analysis of Concrete Columns Subjected to Complex Loading Adam Christopher Morgan, 2018 This study details the development and implementation of a finite element model within a commercial finite element code Abaqus CAE for the analysis of reinforced concrete RC bridge columns containing interlocking spirals subjected to combined loading conditions including axial shear bending and torsional loads including the post peak response The model is a first of its kind attempt at simulating the response of RC columns with continuous spiral transverse reinforcement and subjected to combined loading conditions including torsion The model is utilized to determine the quasi static load deformation response under various proportions of the input loads and displacements The resulting quasi static load deformations i e backbone relationships are compared to those experimentally obtained for three 1 2 scale prototype RC bridge columns subjected to constant axial loading and slow reversed cyclic lateral loading resulting in combined flexural moment shear and torsional moment It was determined that such models can simulate the behavior of such columns with a reasonable level of error for unidirectional loading but accurate torsional response and numerical stability of such models is difficult to obtain due to convergence errors resulting from a combination of inelastic material models and multi body constraints used to couple the motion of the column s constituent pieces together Attempts were made to extend the finite element model to similar RC bridge columns repaired and strengthened with externally bonded fiber reinforced polymer FRP composite jackets however such attempts resulted in convergence failure as the model approached inelastic behavior Abstract page iii

Behavior and Design of Axially Loaded High-strength Composite Columns Ch'eng-chih Ch'en,1993 *ACI Structural Journal* ,2008 Performance of Steel Pipe Pile-to-concrete Bent Cap Connections Subject to Seismic Or High Transverse Loading, Phase II Jerry E. Stephens,2005 The response of a concrete filled steel pipe pile to concrete pile cap connection subjected to extreme lateral loads was experimentally and analytically investigated in this project This connection is part of a bridge support system used by the Montana Department of Transportation that consists of a linear array of piles connected at the top by a concrete pile cap Five 1 2 size models of this connection were tested to failure under monotonically increasing and or cyclic lateral loads The primary attribute of the connection that was varied between tests was the amount and layout of the reinforcing steel in the pile cap The depth of embedment of the pipe pile in the cap was held constant The first tests were done on lightly reinforced pile cap cross sections and failure occurred in the pile caps due to tensile cracking of the concrete and yielding of the reinforcing steel adjacent to the pile In subsequent connections the amount of reinforcing steel in the cap was increased and its arrangement was modified until a plastic hinge occurred in the pipe pile before failure of the cap occurred The behavior of each connection was analyzed using hand calculations strut and tie models and solid finite element models The hand calculations accurately predicted the nature of the failure mechanism for each connection but only poorly predicted the magnitude of the failure load The strut and tie models used in this investigation were created and analyzed using conventional structural analysis software The resulting models offered significant detail relative the response throughout the pile cap but were unable to fully represent yielding of the reinforcing steel and the attendant redistribution of stresses within the cap Sufficiently promising results were obtained relative to predicting the load and location at which inelastic behavior will initiate that this analysis methodology possibly should be pursued further Finally though finite element models were not successfully used to model the damage cycle through cyclic loads as originally hoped they did prove useful for extracting 3D information leading up to a state of permanent damage They also show immediate promise for modeling responses to monotonic load conditions particularly for analysis where concrete damage is not the controlling failure mechanism **Understanding the Confined Concrete Behavior on the Response of Hollow Bridge Columns** Xiao Liang (M.S. in Structural Engineering),Ryan Beck,Sri Sritharan,2015 In seismic design practice hollow concrete columns offer an efficient alternative especially for tall bridge columns The confinement in critical regions of these columns is not well understood and the confinement models developed for solid concrete sections are used to characterize these columns This report identifies several shortcomings in current practice associated with hollow column design Using experimental and analytical means it is shown that the confined concrete behavior in hollow concrete columns is different

from that established for solid sections Recommendations to improve analysis and design of hollow columns are presented with experimental verification Modification to alter the confinement models developed for solid sections and a design example are also provided
