The advent of interferometric synthetic aperture radar for geophysical studies has resulted in the need for accurate, efficient methods of two-dimensional phase unwrapping. Inference of the lost integral number of cycles in phase measurements is critical for three-pass surface deformation studies as well as topographic mapping and can result in an order of magnitude increase in sensitivity for two-pass deformation analysis. While phase unwrapping algorithms have proliferated over the past ten years, two main approaches are currently in use. Each is most useful only for certain restricted applications. All these algorithms begin with the measured gradient of the phase field, which is subsequently integrated to recover the unwrapped phases. The earliest approaches in interferometric applications incorporated residue identification and cuts to limit the possible integration paths, while a second class using least-squares techniques was developed in the early 1990's. We compare the approaches and find that the residue-cut algorithms are quite accurate but do not produce estimates in regions of moderate phase noise. The least-squares methods yield complete coverage but at the cost of distortion in the recovered phase field. A new synthesis approach, combining the cuts from the first class with a least-squares solution, offers greater spatial coverage with less distortion in many instances. © 1998 Optical Society of America 1507-40-3230/98/030586-03

## 1. INTRODUCTION

Algorithms that relate individual phase measurements on a two-dimensional field, motivated largely by interest in interferometric synthetic aperture radar (SAR) techniques, have proliferated over the past ten years.<sup>1-4</sup> These algorithms seek to infer the integral number of cycles lost when a phase measurement is made from a two-dimensional complex signal amplitude observation, which uniquely identifies only the phase value modulo  $2\pi$ . We refer to such algorithms here as phase unwrapping, as distinguished from the use of that term for reconstruction of signal amplitudes from frequency-domain phase data, a common problem associated with one-dimensional signal processing.

We report here a comparison of several of the phase unwrapping algorithms in more common use today and identify and contrast the strengths and weaknesses of each. We also present a synthesis approach that combines some of the more effective features of the existing algorithms and can extend the range of phase unwrapping situations amenable to automated solution. Rather than revolutionize present capabilities, these new algorithms represent another approach for phase unwrapping procedures that aid in some situations where the existing algorithms fare poorly. Because we (1) do not review each existing algorithm comprehensively, (2) do propose new variations of the algorithms suited to particular styles of input data, and (3) do not believe that the existing set of approaches is the final word on phase unwrapping procedures, this article serves more as a progress re-

port rather than as a review of phase unwrapping procedures.

The advent of interferometric SAR for geophysical studies, in particular, has resulted in the need for accurate, efficient methods of two-dimensional phase unwrapping. Radar methods for fast and precise measurement of topographic data,<sup>5,6</sup> determination of centimeter-level surface deformation fields,<sup>7-9</sup> and surface velocity fields<sup>10,11</sup> all require that the relative phases over large areas be known. Strictly speaking, each of these techniques requires, in addition, knowledge of the absolute phase values;<sup>12</sup> however, in practice contextual clues or known fiducial values (tie points) often permit geophysical inference with only the relative phases, given that the phase field is unwrapped.

Although many insights into underlying surface processes may be obtained by visual inspection of the initial, wrapped radar interferogram,<sup>13,14</sup> this unwrapping by eye may be applied only to simple phase fields without significant and complicated structure. Moreover, automated topographic mapping approaches and the application of three-pass deformation algorithms are precluded by the necessity of human interaction on a pixel-by-pixel level with the interferometric data. For instance, even a small-area topographic map may contain millions of meter-spaced posts. Accuracy also drives the requirement. In regions of finely spaced fringes, it may be difficult to estimate the phase manually to better than a large fraction of a cycle accuracy, whereas performance of the radar system itself allows accuracies corresponding to

desired in some other applications such as frequency estimation from undersampled waveforms with its applications for example phase unwrapping in radar signal processing and sensor networks Recently a robust phase unwrapping algorithm has been proposed that has already found applications in multi baseline multifrequency multi speed multi stepped frequency multi pulse repetition frequency SAR imaging for moving targets Regarding the computational complexity of this robust phase unwrapping algorithm an efficient implementation is developed to reduce the two dimensional searching of its original into a one dimensional searching and therefore reduces the complexity significantly What is more motivated from the robust phase unwrapping algorithm a general form of robust CRT is proposed i e robust reconstruction of general large integers from their remainders with errors This case often occurs in practical applications that is the reason why a robust solution is urgently needed In terms of reconstruction of large integers from remainders it is not restricted to co prime moduli and this unique reconstruction is possible if and only if the large integers are less than the least common multiple lcm of all the moduli Note that this proposed algorithm is for a general real number for those with zero fractional errors the algorithm then leads to a fast robust CRT Further some applications based on this robust algorithm are developed including a robust Doppler ambiguity resolution using multiple paired pulse repetition frequencies PRF This new algorithm is based on this robust phase unwrapping algorithm and the Ferrari B erenguer Alengrin FBA method using multiple pulse repetition frequencies PRF Our simulation results show that the newly proposed algorithm significantly outperforms the FBA method and is also better than the robust phase unwrapping algorithm Moreover another important topic and application location and imaging of elevated moving targets using multiple frequency velocity synthetic aperture radar SAR is well investigated and proposed In this dissertation we propose an antenna array approach with cross track interferometry in which multiple wavelength signals are transmitted It is shown that our proposed multiple frequency interferometric velocity SAR MFIn VSAR by applying our proposed robust phase unwrapping algorithm can locate both slowly and fast moving elevated targets correctly An integrated MFIn VSAR algorithm for moving target imaging is also presented
