

Lecture 2: Modern Flow of Control

1. Motivation

Normally, a program executes statements from first to last. The first statement is executed, then the second, then the third, and so on, until the program reaches its end. Sometimes, a computer program *looks* wouldn't for very useful if it ran the same sequence of statements every time it was run. It would be nice to be able to change which statements run and when, depending on the circumstances. For example, if a program checks if the for the number of days a certain word appears, it should be able to give the correct count no matter what the word being given is. Or, a computer game should move the player's character around when the player wants, the need to be able to alter the order in which a program's statements are executed, the control flow.

2. Control Structures

Control structures are portions of program code that execute statements either once and depending on the circumstances, execute these statements in a certain way. There are typically two kinds: conditionals and loops.

2.1 Conditionals

In order for a program to change its behavior depending on the input, there must a way to test that input. Conditionals allow the program to check the values of variables and to execute (or not execute) certain statements. C++ has if and switch-case conditional structures.

2.1.1 Operators

Conditionals use two kinds of special operators: relational and logical. These are used to determine whether some condition is true or false.

The relational operators are used to test a relation between two expressions:

| Operator | Meaning |
|----------|--------------------------|
| > | Greater than |
| >= | Greater than or equal to |
| < | Less than |
| <= | Less than or equal to |
| == | Equal to |
| != | Not equal to |

They work the same as the arithmetic operators (e.g., $4 < 5$) but return a Boolean value of either true or false, indicating whether the relation holds for those. An expression that returns either true or false is called a Boolean expression. For example, if the variables x and y have been set to 5 and 1, respectively, then $x < y$ returns true. Similarly, $x <= y$ returns false.

The logical operators are often used to combine relational expressions into more complicated Boolean expressions.
