

Reliability Analysis of Centrifugal Pumps System Justifies Improvements in Gas Plant

*By Fernando Vicente, Maintenance and Reliability Integrity Engineer
ABB Service, Argentina*

INTRODUCTION

Over the past several years, reliability has become an ever-increasingly important topic and component in the organizational continuous improvement tool box. Higher plant reliability reduces process and equipment failures costs as failure disruption decreases production output which in turn limits gross margin. Additionally, equipment failures also increase the probability of having a catastrophic environmental accident and the potential for increasing safety related accidents.

The strong competitive environment between companies to secure business and the current world financial crisis are forcing organizations to explore ways to reduce operating costs. A popular approach to reduce operating costs is to reduce expenditures on equipment maintenance. While results can be obtained by reducing investments in equipment, this approach is very short sighted. It is not unusual that deferred investments will re-surface and cost 2 to 5 times more than if addressed in the early stages of failure development.

The purpose of this paper is to objectively demonstrate that an approach focused on reliability, availability and maintainability prediction will help to detect pieces, equipments and systems that require improvements helping to maintenance managers to make the right decision analyzing a centrifugal pump system in a gas plant.

DEVELOPMENT

The primary function of a NGL Recovery Gas Plant is to recover the rich component of gas (ethane, butane, propane and gasoline) known as "Soup". This soup is dispatched to a fractionating plant where the components are recovered again and then are sold to the market.

The centrifugal pump system analyzed is a critical part of the process, basically is the core of business. The main purpose of the centrifugal pumps is to take the soup out of the main recovery tower to send the NGL (Natural Gas Liquids) to the dispatching area (See Figure-1).

The pumps system is composed by two centrifugal pumps disposed in parallel, one pump is operating and the other pump is waiting to be demanded. The system for the reliability analysis is called "Stand-by redundancy" type 1 of 2, just one pump is in operating mode and the other pump is waiting for failure of the first pump. These are two-stage centrifugal pumps type (WTB) vertically spitted; they are designed for heavy duty in refineries, electric centrals and for general services.
