A New PEMFC Flow Field Plate Optimization Comparison ANSYS Fluent Fuel-cell Simulation Ahmed

Soueidan, 2012 The performance of a new cathode flow field plate located on a PEM fuel cell was compared to an industry standard and optimal serpentine design provided from literature Results were successfully collected through a fuel cell module integrated with the 3D computational fluid dynamics package ANSYS Fluent Contour plots showing a cathode catalyst layer comparison of local current density oxygen molar concentrations water content and the pressure inside of the flow channels were compared with both PEM fuel cell configurations The new flow field plate pattern was shown to distribute more mass species of oxygen more evenly to the reaction site given the same boundary conditions thus contributing to more ideal local current density The net power was determined for both fuel cells which included the pump work in and power out from each fuel cell The new flow field plate was shown through computational power performance results to outperform the conventional flow pattern by up to 2.4% when excluding the effects of pump work and still upheld a positive gain when factoring in this value With an additional 18 corners for improved water management due to the effects of wall adhesion the new bipolar plate was proven to become a new competitor in PEM fuel cell technology Furthermore this thesis gives further insight on PEMFC digital prototyping

Mathematical and Computational Modeling of Polymer Exchange

Membrane Fuel Cells Sehribani Ulusoy, 2012 In this thesis a comprehensive review of fuel cell modeling has been given and based on the review a general mathematical fuel cell model has been developed in order to understand the physical phenomena governing the fuel cell behavior and in order to contribute to the efforts investigating the optimum performance at different operating conditions as well as with different physical parameters The steady state isothermal model presented here accounts for the combined effects of mass and species transfer momentum conservation electrical current distribution through the gas channels the electrodes and the membrane and the electrochemical kinetics of the reactions in the anode and cathode catalyst layers One of the important features of the model is that it proposes a simpler modified pseudo homogeneous agglomerate catalyst layer model which takes the advantage of the simplicity of pseudo homogenous modeling while taking into account the effects of the agglomerates in the catalyst layer by using experimental geometric parameters

published The computation of the general mathematical model can be accomplished in 3D 2D and 1D with the proper assumptions Mainly there are two computational domains considered in this thesis The first modeling domain is a 2D Membrane Electrode Assembly MEA model including the modified agglomerate pseudo homogeneous catalyst layer modeling with consistent treatment of water transport in the MEA while the second domain presents a 3D model with different flow filed designs straight stepped and tapered COMSOL Multiphysics along with Batteries and Fuel Cell Module have been used for 2D 3D model computations while ANSYS FLUENT PEMFC Module has been used for only 3D two phase computation Both models have been validated with experimental data With 2D MEA model the effects of temperature and water content of the membrane as well as the equivalent weight of the membrane on the performance have been addressed 3D COMSOL simulation results showed that the fuel performance can be improved by using flow field designs alleviating the reactant depletion along the channels and supplying more uniform reactant distribution Stepped flow field was found to show better performance when compared to straight and tapered ones ANSYS FLUENT model is evaluated in terms of predicting the two phase flow in the fuel cell components It is proposed that it is not capable of predicting the entire fuel cell polarization due to the lack of agglomerate catalyst layer modeling and well established two phase flow modeling Along with the comprehensive modeling efforts also an analytical model has been computed by using MathCAD and it is found that this simpler model is able to predict the performance in a general trend according to the experimental data obtained for a new novel membrane Therefore it can be used for robust prediction of the cell performance at different operating conditions such as temperature and pressure and the electrochemical properties such as the catalyst loading the exchange current density and the diffusion coefficients of the reactants In addition to the modeling efforts this thesis also presents a very comprehensive literature review on the models developed in the literature so far the modeling efforts in fuel cell sandwich including membrane catalyst layer and gas diffusion layer and fuel cell model properties Moreover a summary of possible directions of research in fuel cell analysis and computational modeling has been presented
