Convex Optimization Via Domain-driven Barriers and Primal-dual Interior-point Methods Mehdi Karimi, 2017 This thesis studies the theory and implementation of infeasible start primal dual interior point methods for convex optimization problems Convex optimization has applications in many fields of engineering and science such as data analysis control theory signal processing relaxation and randomization and robust optimization In addition to strong and elegant theories the potential for creating efficient and robust software has made convex optimization very popular Primal dual algorithms have yielded efficient solvers for convex optimization problems in conic form over symmetric cones linear programming LP second order cone programming SOCP and semidefinite programming SDP However many other highly demanded convex optimization problems lack comparable solvers To close this gap we have introduced a general optimization setup called emph Domain Driven that covers many interesting classes of optimization Domain Driven means our techniques are directly applied to the given good formulation without a forced reformulation in a conic form Moreover this approach also naturally handles the cone constraints and hence the conic form A problem is in the Domain Driven setup if it can be formulated as minimizing a linear function over a convex set where the convex set is equipped with an efficient self concordant barrier with an easy to evaluate Legendre Fenchel conjugate We show how general this setup is by providing several interesting classes of examples LP SOCP and SDP are covered by the Domain Driven setup More generally consider all convex cones with the property that both the cone and its dual admit efficiently computable self concordant barriers Then our Domain Driven setup can handle any conic optimization problem formulated using direct sums of these cones and their duals Then we show how to construct interesting convex sets as the direct sum of the epigraphs of univariate convex functions This construction as a special case contains problems such as geometric programming p norm optimization and

entropy programming the solutions of which are in great demand in engineering and science Another interesting class of convex sets that optimization over it is contained in the Domain Driven setup is the generalized epigraph of a matrix norm This as a special case allows us to minimize the nuclear norm over a linear subspace that has applications in machine learning and big data Domain Driven setup contains the combination of all the above problems for example we can have a problem with LP and SDP constraints combined with ones defined by univariate convex functions or the epigraph of a matrix norm We review the literature on infeasible start algorithms and discuss the pros and cons of different methods to show where our algorithms stand among them This thesis contains a chapter about several properties for self concordant functions Since we are dealing with general convex sets many of these properties are used frequently in the design and analysis of our algorithms We introduce a notion of duality gap for the Domain Driven setup that reduces to the conventional duality gap if the problem is a conic optimization problem and prove some general results Then to solve our problems we construct infeasible start primal dual central paths A critical part in achieving the current best iteration complexity bounds is designing algorithms that follow the path efficiently The algorithms we design are predictor corrector algorithms Determining the status of a general convex optimization problem as being unbounded infeasible having optimal solutions etc is much more complicated than that of LP We classify the possible status seven possibilities for our problem as solvable strictly primal dual feasible strictly and strongly primal infeasible strictly and strongly primal unbounded and ill conditioned We discuss the certificates our algorithms return heavily relying on duality for each of these cases and analyze the number of iterations required to return such certificates For infeasibility and unboundedness we define a weak and a strict detector We prove that our algorithms return these certificates solve the problem in polynomial time with the current best theoretical complexity bounds The complexity results are new for the infeasible start models used The different patterns that can be detected by our algorithms and the iteration complexity bounds for them are comparable to the current best results available for infeasible start conic optimization which to the best of our knowledge is the work of Nesterov Todd Ye 1999 In the applications computation and software front based on our algorithms we created a Matlab based code called DDS that solves a large class of problems including LP SOCP SDP quadratically constrained quadratic programming QCQP geometric programming entropy programming and more can be added Even though the code is not finalized this chapter shows a glimpse of possibilities The generality of the code lets us solve problems that CVX a modeling system for convex optimization does not even recognize as convex The DDS code accepts constraints representing the epigraph of a matrix norm which as we mentioned covers minimizing the nuclear norm over a linear subspace For acceptable classes of convex optimization problems we explain the format of the input We give the formula for computing the gradient and Hessian of the corresponding self concordant barriers and their Legendre Fenchel conjugates and discuss the methods we use to compute them efficiently and robustly We present several numerical results of applying the DDS code to our constructed examples

and also problems from well known libraries such as the DIMACS library of mixed semidefinite quadratic linear programs We also discuss different numerical challenges and our approaches for removing them

Convex Optimization & Euclidean Distance Geometry Jon Dattorro, 2005 The study of Euclidean distance matrices EDMs fundamentally asks what can be known geometrically given only distance information between points in Euclidean space Each point may represent simply location or abstractly any entity expressible as a vector in finite dimensional Euclidean space The answer to the question posed is that very much can be known about the points the mathematics of this combined study of geometry and optimization is rich and deep Throughout we cite beacons of historical accomplishment The application of EDMs has already proven invaluable in discerning biological molecular conformation The emerging practice of localization in wireless sensor networks the global positioning system GPS and distance based pattern recognition will certainly simplify and benefit from this theory We study the pervasive convex Euclidean bodies and their various representations In particular we make convex polyhedra cones and dual cones more visceral through illustration and we study the geometric relation of polyhedral cones to nonorthogonal bases biorthogonal expansion We explain conversion between halfspace and vertex descriptions of convex cones we provide formulae for determining dual cones and we show how classic alternative systems of linear inequalities or linear matrix inequalities and optimality conditions can be explained by generalized inequalities in terms of convex cones and their duals The conic analogue to linear independence called conic independence is introduced as a new tool in the study of classical cone theory the logical next step in the progression linear affine conic Any convex optimization problem has geometric interpretation This is a powerful attraction the ability to visualize geometry of an optimization problem We provide tools to make visualization easier The concept of faces extreme points and extreme directions of convex Euclidean bodies is explained here crucial to understanding convex optimization The convex cone of positive semidefinite matrices in particular is studied in depth We mathematically interpret for example its inverse image under affine transformation and we explain how higher rank subsets of its boundary united with its interior are convex The Chapter on Geometry of convex functions observes analogies between convex sets and functions The set of all vector valued convex functions is a closed convex cone Included among the examples in this chapter we show how the real affine function relates to convex functions as the hyperplane relates to convex sets Here also pertinent results for multidimensional convex functions are presented that are largely ignored in the literature tricks and tips for determining their convexity and discerning their geometry particularly with regard to matrix calculus which remains largely unsystematized when compared with the traditional practice of ordinary calculus Consequently we collect some results of matrix differentiation in the appendices The Euclidean distance matrix EDM is studied its properties and relationship to both positive semidefinite and Gram matrices We relate the EDM to the four classical axioms of the Euclidean metric thereby observing the existence of an infinity of axioms of the Euclidean metric beyond the triangle inequality We proceed by deriving the fifth Euclidean axiom and then explain why furthering this

endeavor is inefficient because the ensuing criteria while describing polyhedra grow linearly in complexity and number. Some geometrical problems solvable via EDMs (Euclidean Distance Matrices) are posed as convex optimization and methods of solution are represented. eg we generate a recognizable isotonic map of the United States using only comparative distance information (no distance information only distance inequalities). We offer a new proof of the classic Schoenberg criterion that determines whether a candidate matrix is an EDM. Our proof relies on fundamental geometry assuming any EDM must correspond to a list of points contained in some polyhedron possibly at its vertices and vice versa. It is not widely known that the Schoenberg criterion implies nonnegativity of the EDM entries (proved here). We characterize the eigenvalues of an EDM matrix and then devise a polyhedral cone required for determining membership of a candidate matrix in Cayley Menger form to the convex cone of Euclidean distance matrices (EDM cone). ie a candidate is an EDM if and only if its eigenspectrum belongs to a spectral cone for EDM N . We will see spectral cones are not unique. In the chapter EDM cone we explain the geometric relationship between the EDM cone, two positive semidefinite cones, and the elliptope. We illustrate geometric requirements in particular for projection of a candidate matrix on a positive semidefinite cone that establish its membership to the EDM cone. The faces of the EDM cone are described but still open is the question whether all its faces are exposed as they are for the positive semidefinite cone. The classic Schoenberg criterion relating EDM and positive semidefinite cones is revealed to be a discretized membership relation, a generalized inequality, a new Farkas-like lemma between the EDM cone and its ordinary dual. A matrix criterion for membership to the dual EDM cone is derived that is simpler than the Schoenberg criterion. We derive a new concise expression for the EDM cone and its dual involving two subspaces and a positive semidefinite cone. Semidefinite programming is reviewed with particular attention to optimality conditions of prototypical primal and dual conic programs, their interplay, and the perturbation method of rank reduction of optimal solutions (extant but not well known). We show how to solve a ubiquitous platonic combinatorial optimization problem from linear algebra: the optimal Boolean solution x to $Ax \leq b$ via semidefinite program relaxation. A three-dimensional polyhedral analogue for the positive semidefinite cone of 3×3 symmetric matrices is introduced as a tool for visualizing in 6 dimensions. In EDM proximity we explore methods of solution to a few fundamental and prevalent Euclidean distance matrix proximity problems: the problem of finding that Euclidean distance matrix closest to a given matrix in the Euclidean sense. We pay particular attention to the problem when compounded with rank minimization. We offer a new geometrical proof of a famous result discovered by Eckart Young in 1936 regarding Euclidean projection of a point on a subset of the positive semidefinite cone comprising all positive semidefinite matrices having rank not exceeding a prescribed limit ρ . We explain how this problem is transformed to a convex optimization for any rank ρ .
