Forecasting of the financial market have been an attractive topic to scholars and researchers from various academic fields. The financial market is an abstract concept where financial commodities such as stocks, bonds, and precious metals transactions happen between buyers and sellers. In the present scenario of the financial market world, especially in the stock market, forecasting the trend or the price of stocks using machine learning techniques and artificial neural networks are the most attractive issue to be investigated. As Giles explained, financial forecasting is an instance of signal processing problem which is difficult because of high noise, small sample size, non-stationary, and non-linearity. The noisy characteristics mean the incomplete information gap between past stock trading price and volume with a future price. The stock market is sensitive with the political and macroeconomic environment. However, these two kinds of information are too complex and unstable to gather. The above information that cannot be included in features are considered as noise. The sample size of financial data is determined by real-world transaction records. On one hand, a larger sample size refers to a longer period of transaction records; on the other hand, large sample size increases the uncertainty of financial environment during the 2-sample period. In this project, we use stock data instead of daily data in order to reduce the probability of uncertain noise and relatively increase the sample size within a certain period of time. By non-stationarity, one means that the distribution of stock data is various during time, changing. Non-linearity implies that feature correlation of different individual stocks is various.
