

# FUNDAMENTALS OF METAL FORMING

## Metal Forming

- Large group of manufacturing processes in which plastic deformation is used to change the shape of metal workpieces
- The tool, usually called a die, applies stresses that exceed yield strength of metal
- The metal takes a shape determined by the geometry of the die

## Stresses in Metal Forming

- Stresses to plastically deform the metal are usually **compressive**  
Examples: forging, rolling, extrusion
- However, some forming processes:  
    Stretch the metal (**tensile** stresses)  
    Others bend the metal (tensile and compressive)  
    Still others apply **shear** stresses

\*Tensile - capable of being stretched or extended; ductile.  
\*Shear stress - exists when two parts of a material tend to slide across each other in any typical plane of shear upon application of force parallel to that plane.

## Material Properties in Metal Forming

Desirable material properties:

- **Low yield strength and high ductility**

\*Yield strength refers to an indication of maximum stress that can be developed in a material without causing plastic deformation.

These properties are affected by temperature:

**Ductility increases and yield strength decreases** when work temperature is raised

Other factors:

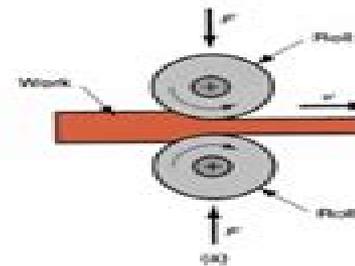

Strain rate and friction

## Bulk Deformation Processes

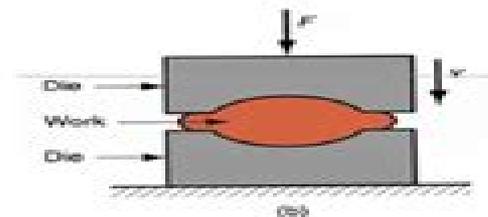

- Characterized by significant deformations and massive shape changes
- "Bulk" refers to workparts with relatively low surface area-to-volume ratios
- Starting work shapes include cylindrical billets and rectangular bars
