

GEOMETRY - Part 1

segments, lines, planes, geometric formulas

GEOMETRY HISTORY

Geometry means earth measurement. Early people used their basic knowledge of geometry to build roads, bridges, pyramids, and irrigation systems. The more formal study of geometry today is based on an interest in logical reasoning and mathematics, rather than in measurement alone. Euclid (c.300 B.C.), a legendary Greek geometer, was a brilliant volunteer set of books named **The Elements**, in which the geometric relationships were derived through deductive reasoning. Thus, the formal geometry studied today is often called **Euclidean geometry**. This geometry is also called **plane geometry** because the relationships deal with flat surfaces. Geometry has useful real terms, defined terms, postulates (statements that have not been proved, but have "worked" for thousands of years), and theorems (relationships that have been mathematically and logically proven).

GEOMETRIC FORMULAS

Perimeter: The perimeter, P , of a two-dimensional shape is the sum of all side lengths. Area: The area, A , of a two-dimensional shape is the number of square units that can be put in the shape enclosed by the sides. **Surface Area:** The surface area is the sum of the area of all the faces of a three-dimensional object. **Volume:** The volume, V , of a three-dimensional object is the number of cubic units that can be put in the object enclosed by all the sides.

Square Area:
 An $n \times n$ square has n^2 square units.
 Example: A 4x4 square has 16 square units.

Rectangle Area:
 An $n \times m$ rectangle has $n \times m$ square units.
 Example: A 4x6 rectangle has 24 square units.

Triangle Area:
 An $n \times m$ triangle has $\frac{1}{2} n \times m$ square units.
 Example: A 4x6 triangle has 12 square units.

Parallelogram Area:
 An $n \times m$ parallelogram has $n \times m$ square units.
 Example: A 4x6 parallelogram has 24 square units.

Trapezoid Area:
 An n_1 by n_2 by m_1 by m_2 trapezoid has $\frac{1}{2} (n_1 + n_2) \times (m_1 + m_2)$ square units.
 Example: A 4x6 by 2x4 trapezoid has 20 square units.

Circle Area:
 An r circle has πr^2 square units.
 Example: A 4 radius circle has 50.24 square units.
 Circumference: $C = 2\pi r$. Example: A 4 radius circle has 25.12 units.

Pythagorean Theorem:
 If a right triangle has legs a and b , and hypotenuse c , then $a^2 + b^2 = c^2$.

Rectangle Prism Volume:
 A $n \times m \times h$ prism has $n \times m \times h$ cubic units.
 Example: A 4x6x2 prism has 48 cubic units.

Cube Volume:
 An $n \times n \times n$ cube has n^3 cubic units.
 Example: A 4x4x4 cube has 64 cubic units.

Cylinder Volume:
 An r by h cylinder has $\pi r^2 h$ cubic units.
 Example: A 4 radius by 2 height cylinder has 100.48 cubic units.

Cone Volume:
 An r by h cone has $\frac{1}{3} \pi r^2 h$ cubic units.
 Example: A 4 radius by 2 height cone has 100.48 cubic units.

Triangular Prism Volume:
 An n by m by h triangular prism has $\frac{1}{2} n \times m \times h$ cubic units.
 Example: A 4x6x2 triangular prism has 24 cubic units.

Rectangular Pyramid Volume:
 An n by m by h pyramid has $\frac{1}{3} n \times m \times h$ cubic units.
 Example: A 4x6x2 pyramid has 16 cubic units.

Sphere Volume:
 An r sphere has $\frac{4}{3} \pi r^3$ cubic units.
 Example: A 4 radius sphere has 268.08 cubic units.

DESCRIPTIONS OF UNDEFINED TERMS

Point

- A point may be described as a location with no length, no width, and no depth.
- A point is a letter named with a capital letter. It is usually located by writing a dot above the name of a point, although the points cannot really be drawn because they have no dimensions. (See Examples 1-4, below.)

Line

- A line may be described as a set of points going straight on forever in two opposite directions. Lines are straight and uncurved. There is no end to a line. The phrase "straight line" is not necessary because straight is not straight if it curves. Lines are flat, but not with any depth. Lines cannot be bent or curved. They have length and depth. Exaggerations of lines are drawn in all planes as well as in space so that the line has no end.
- Lines are usually named by one of two ways. The line containing points K and N may be named by either:
 - Using only the letters K and N above the line, as shown above. (For example, \overleftrightarrow{KN} or \overleftrightarrow{NK} .) The order of the letters doesn't matter; the line indicator above the capital letters always points horizontally from left to right and never in any other direction. It is the usual direction of the points in space that determines the location and direction of the real line, not the direction of the line indicator above the capital letters on the diagram.
 - By using the letters l and m with a number subscript, for example, l_1 or l_2 .

C: Lines in Euclidean geometry, points and the geometry of three planes, and geometric properties of lines can be described. See Algebra - Part 2.

Planes

- A plane may be described as a set of points going on forever in all directions except for one dimension that causes depth. Imagine the very surface of a perfectly flat piece of paper extending on forever in every direction but having no thickness at all. This could be a flat structure such that when any two points in this plane are connected by a line, all points on the line are also in the plane. Planes have length and width, but no depth.
- Planes are usually referred to as "plane ABC " or "plane ABC (any 3 points on the plane that are not on the same line)" or "the plane containing \dots (whatever points in the diagram)". Planes cannot be drawn. Representations of planes are usually drawn as parallelograms, either with the arrows indicating that the plane goes on forever or without the arrows even though the points do go on forever.

Postulates

- Postulates are statements that have been used and accepted for centuries without formal proof. These are postulates:
- A line contains at least 2 points, and any 2 points locate exactly one line.

- A plane contains at least 3 points that are not all on the same line, and any 3 points that are not on the same line locate exactly one plane. Therefore, a line and one point not on the line also locate exactly one plane.

C: Any 3 points locate at least one plane.

- Any 2 points of a line are in a plane, and the line is in the plane, or, if two points are in a plane then the line containing the two points is also in the plane.

- Any 2 planes intersect, and their intersection is a line.

DEFINED TERMS

There are many defined terms of plane geometry. The definitions of these terms will be given by topic, groups throughout the study guide rather than grouped by one big list.

Plane: Postulates for several are relationships and statements that have worked for centuries and are accepted as true mathematically. These are relationships and statements that have been proved mathematically. Postulates and theorems are given throughout this guide. They also are stated under the various topics of geometry. Sometimes they are defined as postulates or theorems, and sometimes they are simply stated and not labeled.

Space

Space is the set of all points. Space goes on forever in every direction, with infinite length, width, and depth. Space has no special location. It is simply defined as space. Space contains at least 4 points that are not all on the same plane.

General Terms

- Two segments overlap on the same segment and therefore, after some movement of the shapes they can be made to fit exactly on top of each other.
- Non-Overlapping parts of overlapping polygons are congruent:** that is, if two polygons have two angles around in one place perfectly, then the parts that match correspondingly are congruent.
